Beyond Contact: Engineering Super-Binders via Residue Correlation

A rational design framework for targeting MERS-CoV PLpro with 27,500-fold affinity enhancement.

The Subject

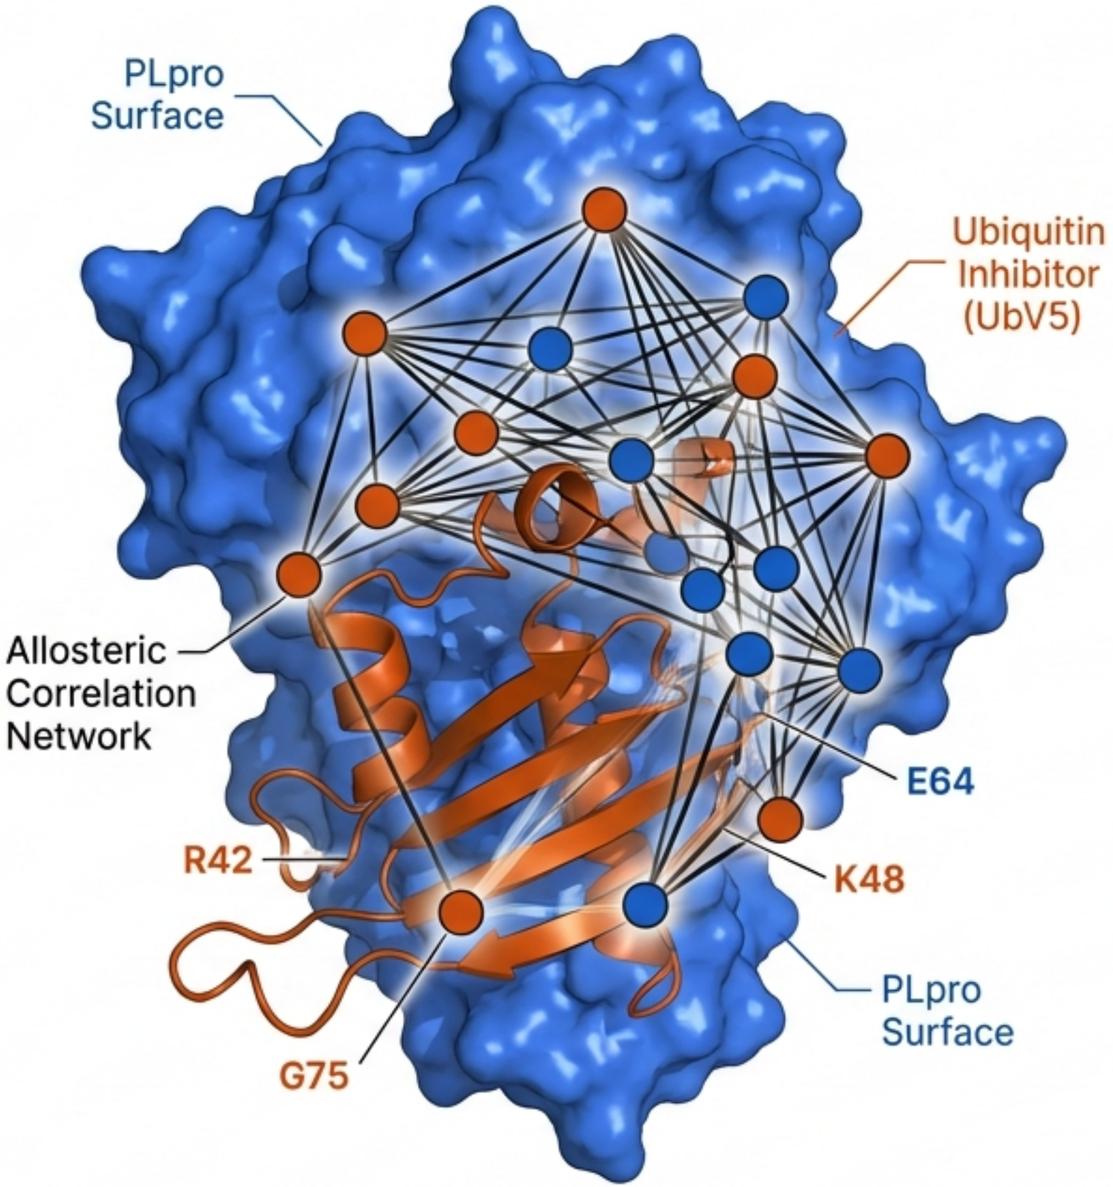
Targeting MERS-CoV Papain-like protease (PLpro), the viral enzyme driving replication.

The Method

Mapping dihedral angle correlation networks to identify synchronized residue motion.

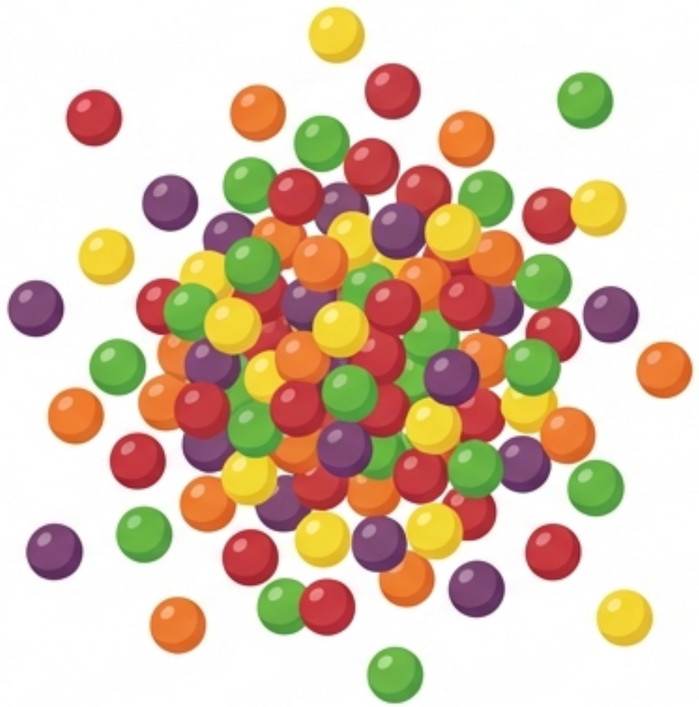
The Outcome

Engineering Ubiquitin (UbV5) into a nanomolar inhibitor.



The Stability Trade-off in Traditional Protein Engineering

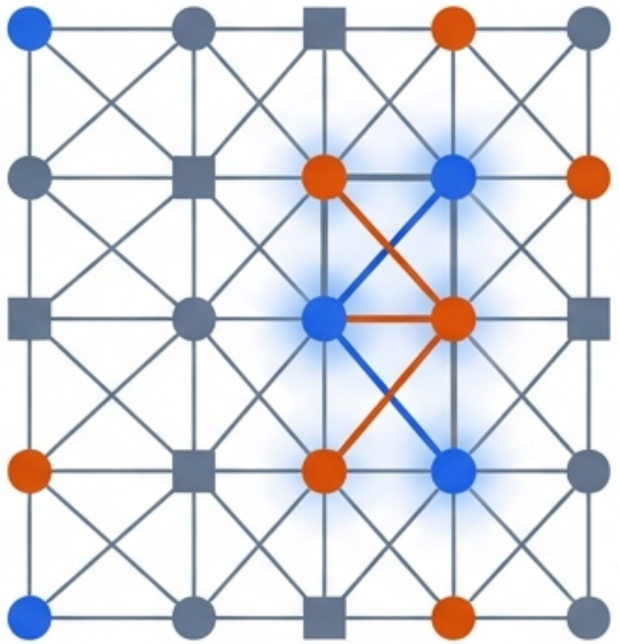
The Status Quo: Random Screening



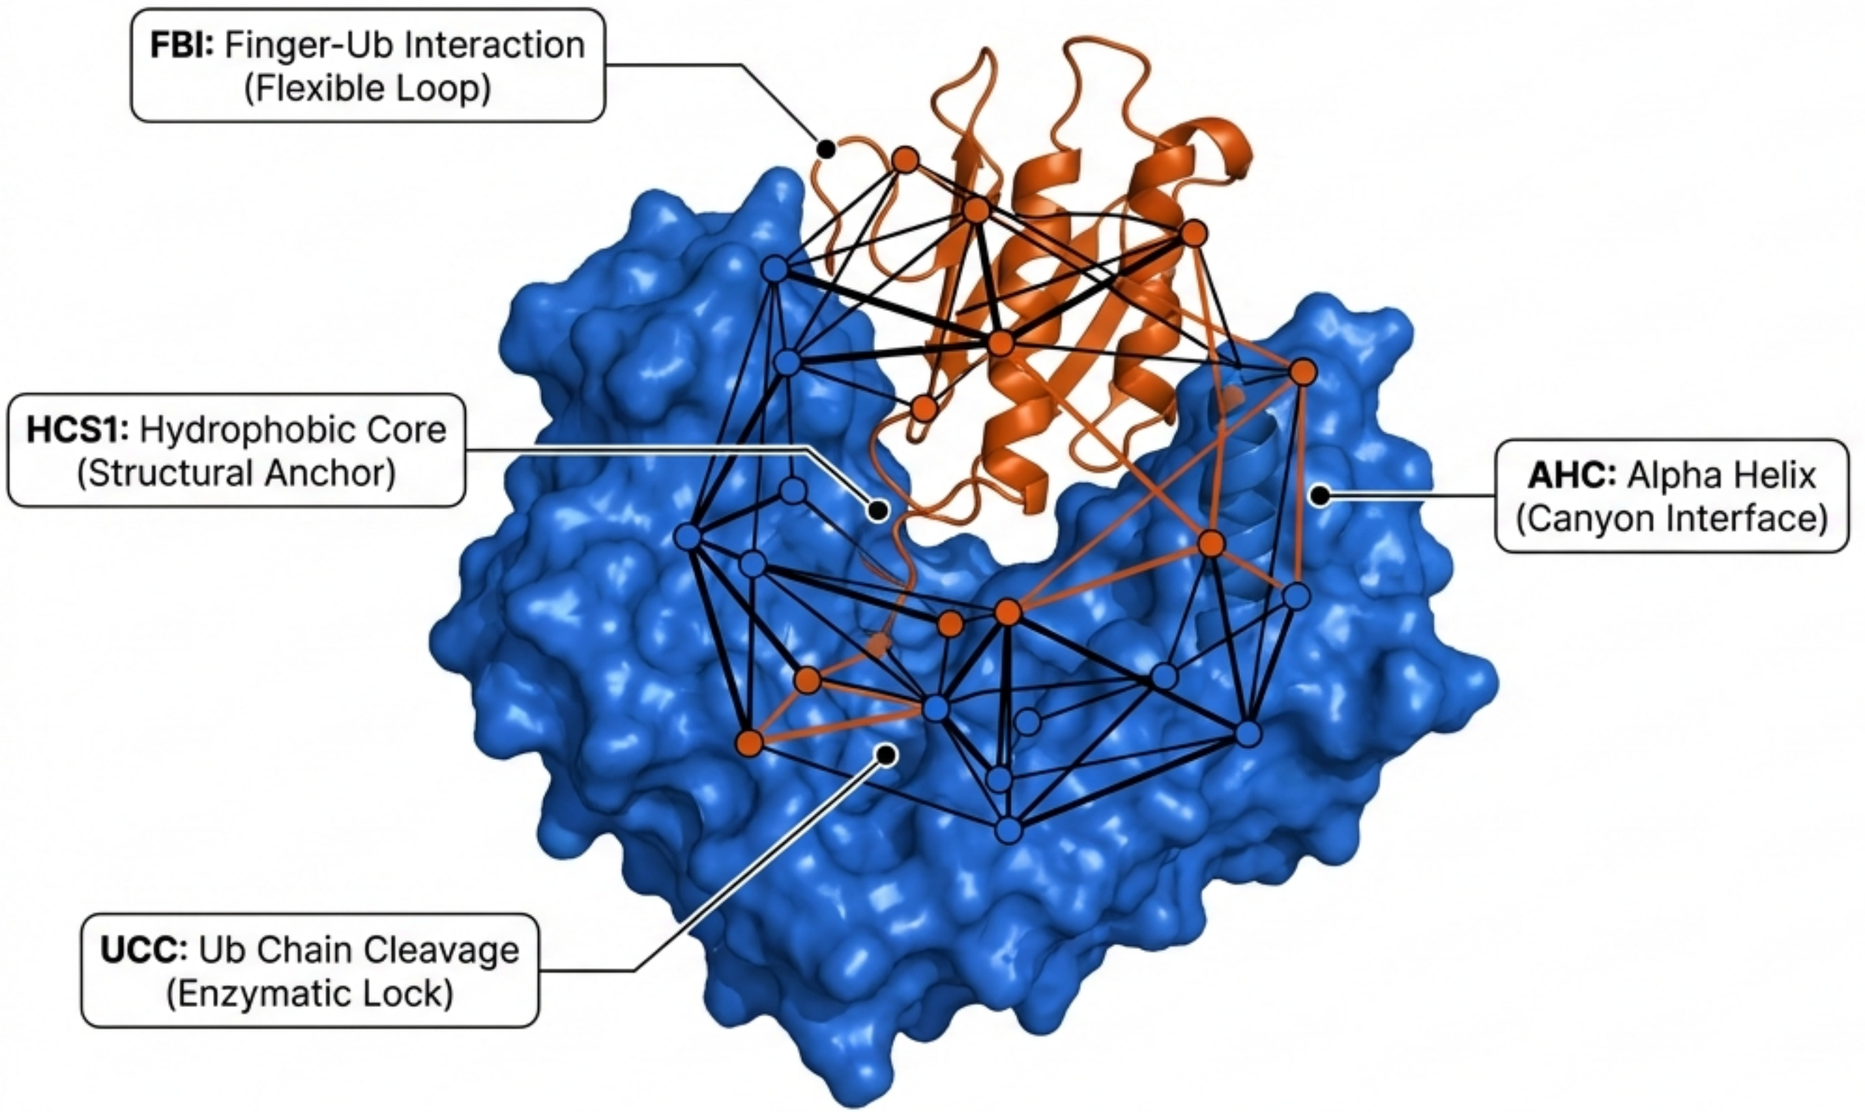
- **Method:** High-throughput Phage Display.
- **Strategy:** Random mutagenesis (Shotgun approach).
- **Drawback:** Requires 10-15 mutations, often leading to unstable proteins that denature <80°C.

The Innovation: Rational Design

- **Method:** Dihedral Angle Correlation Analysis.
- **Strategy:** Targeted modification of ‘Hub’ residues.
- **Advantage:** Minimizes mutations (only 5 needed) to maximize stability and affinity.



Mapping the Invisible Strings of Protein Dynamics

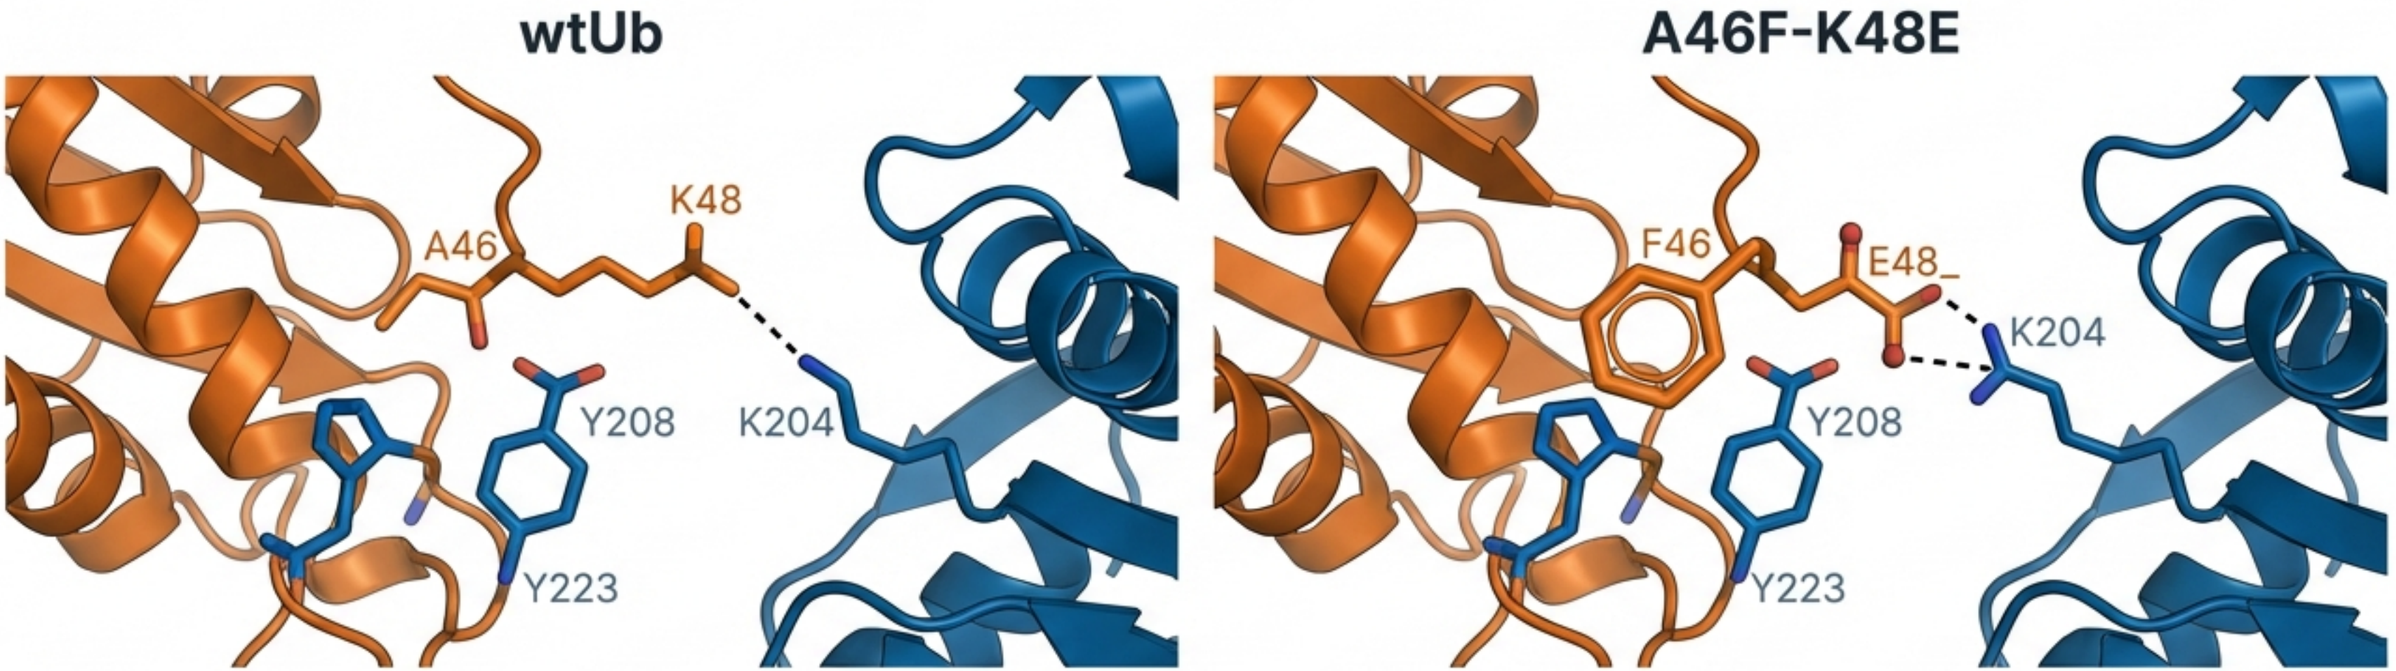


The Butterfly Effect

500ns Molecular Dynamics (MD) simulations reveal that modifying a "hub" residue triggers conformational changes in distal regions (Correlation $r > 0.3$).

Evolution Stage I: Fixing the Foundation (UbV2)

Optimizing the Hydrophobic Core (HCS1) for bulk and charge



Mutation A46F (Alanine → Phenylalanine)

Introduces a bulky aromatic ring to create new pi-pi interactions with PLpro residues Y208 and Y223.

Mutation K48E (Lysine → Glutamate)

Reverses charge to fix electrostatic repulsion. The new Glutamate (negative) attracts PLpro's K204 (positive).

250-fold inhibition increase. IC_{50}: ~0.2 μM.

Evolution Stage II: Stabilizing the Flexible Finger (UbV3)

Freezing the dynamic loop to achieve nanomolar specificity.

The Challenge:

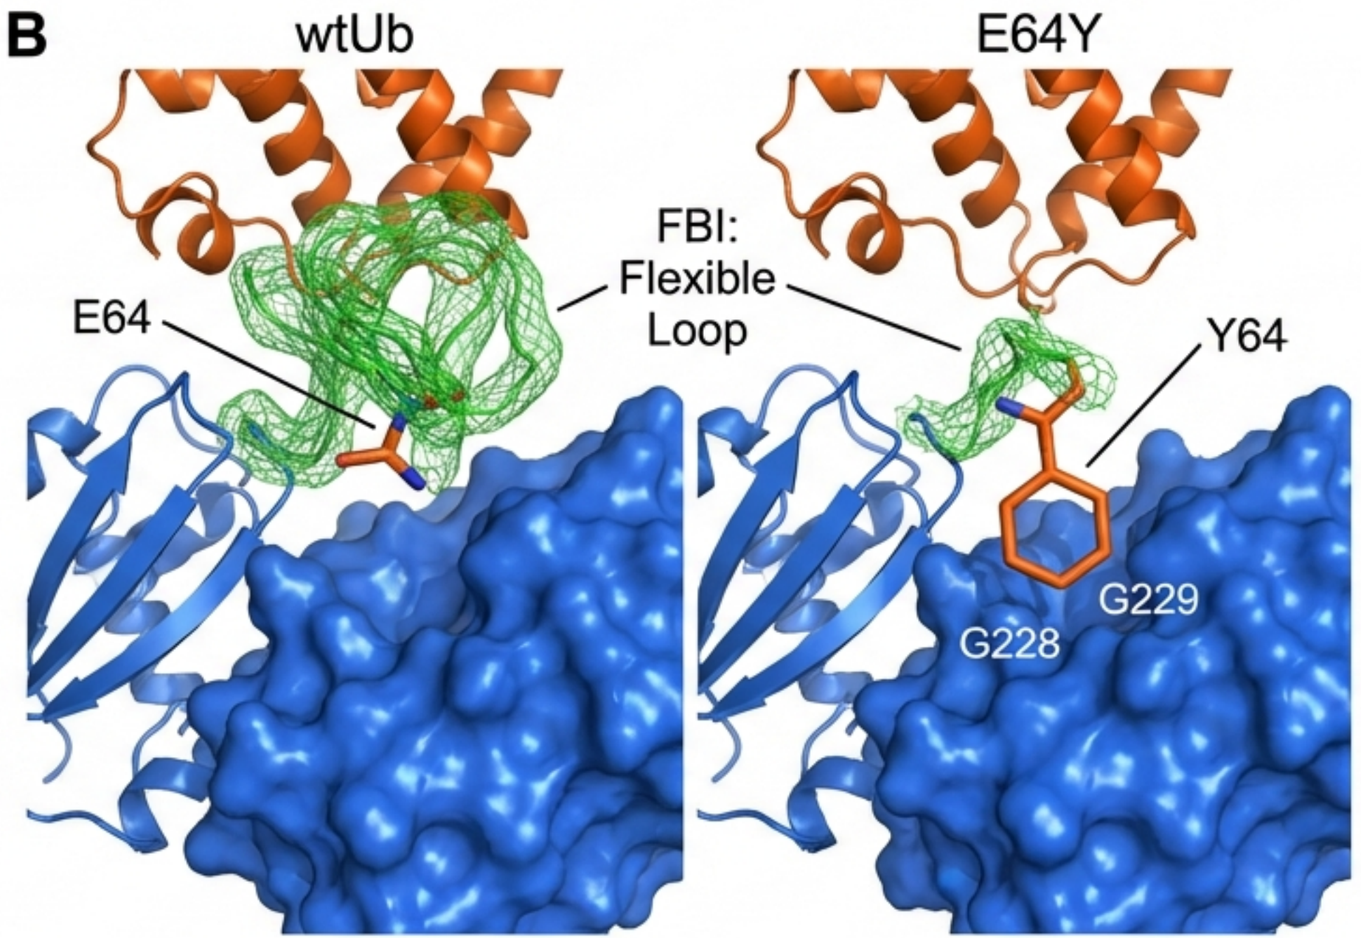
The Finger-Ub Interaction (FBI) region is highly flexible (high RMSF), making it a moving target.

The Solution: Mutation E64Y

Replacing Glutamate with Tyrosine (Y) introduces a large hydrophobic ring that locks into PLpro's G228/G229, acting as a molecular anchor.

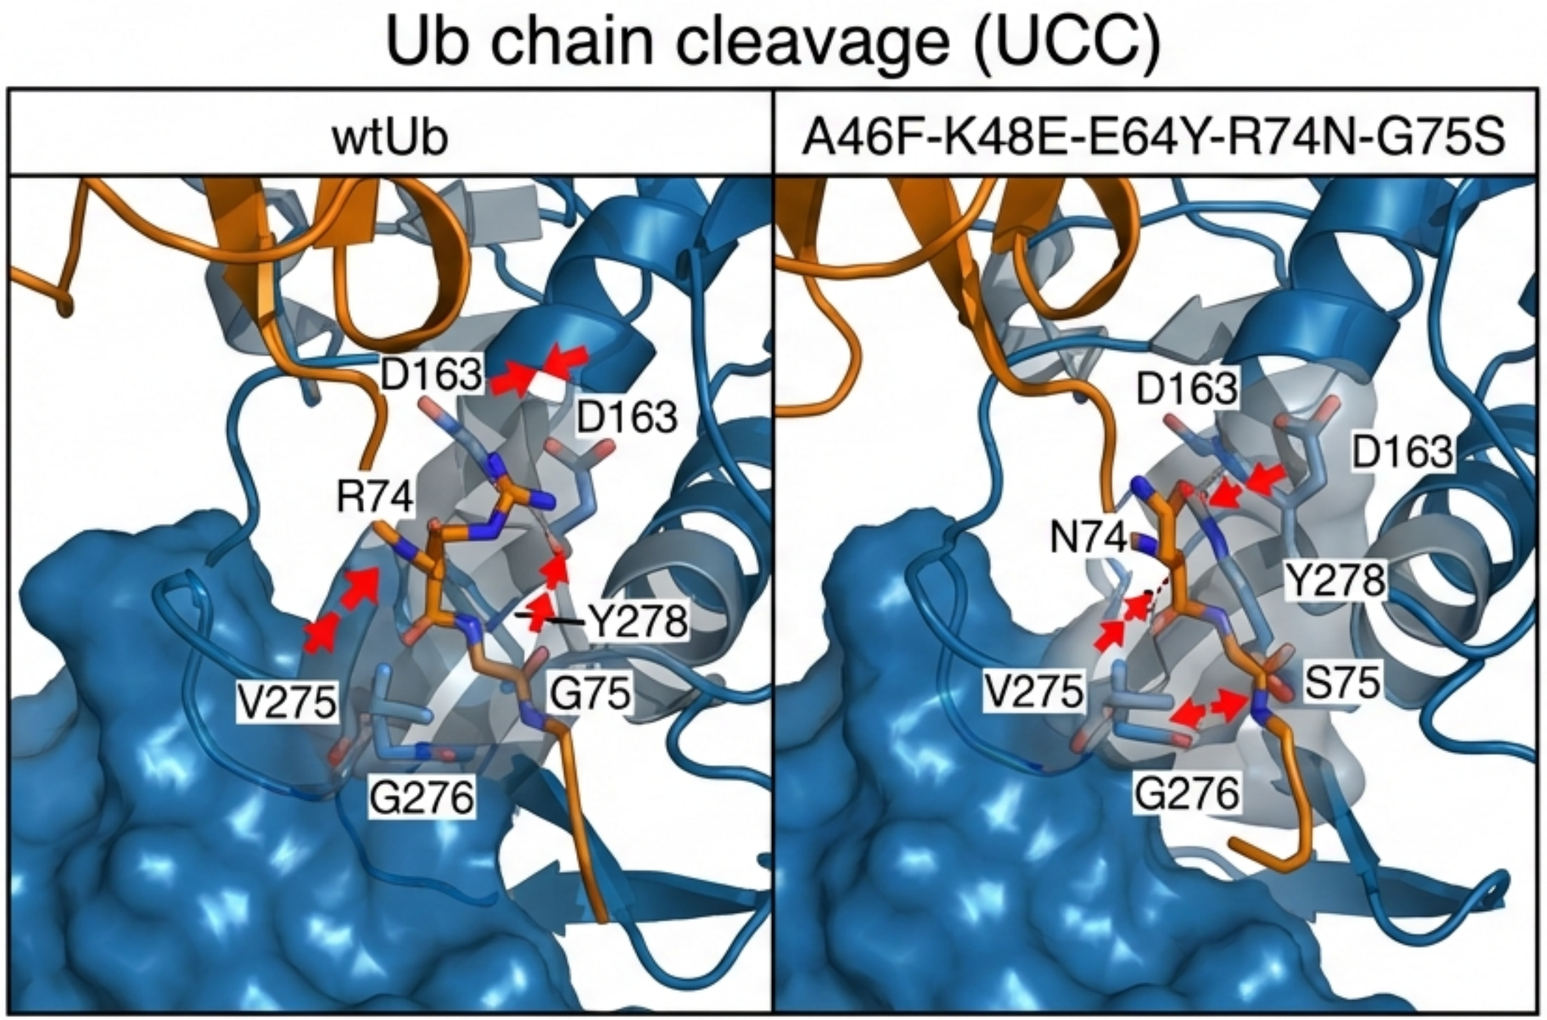
Result:

Massive jump in specificity. KD drops to 2.77 nM.



Evolution Stage III: Jamming the Lock (UbV5)

Modifying the cleavage site to create the ultimate inhibitor.

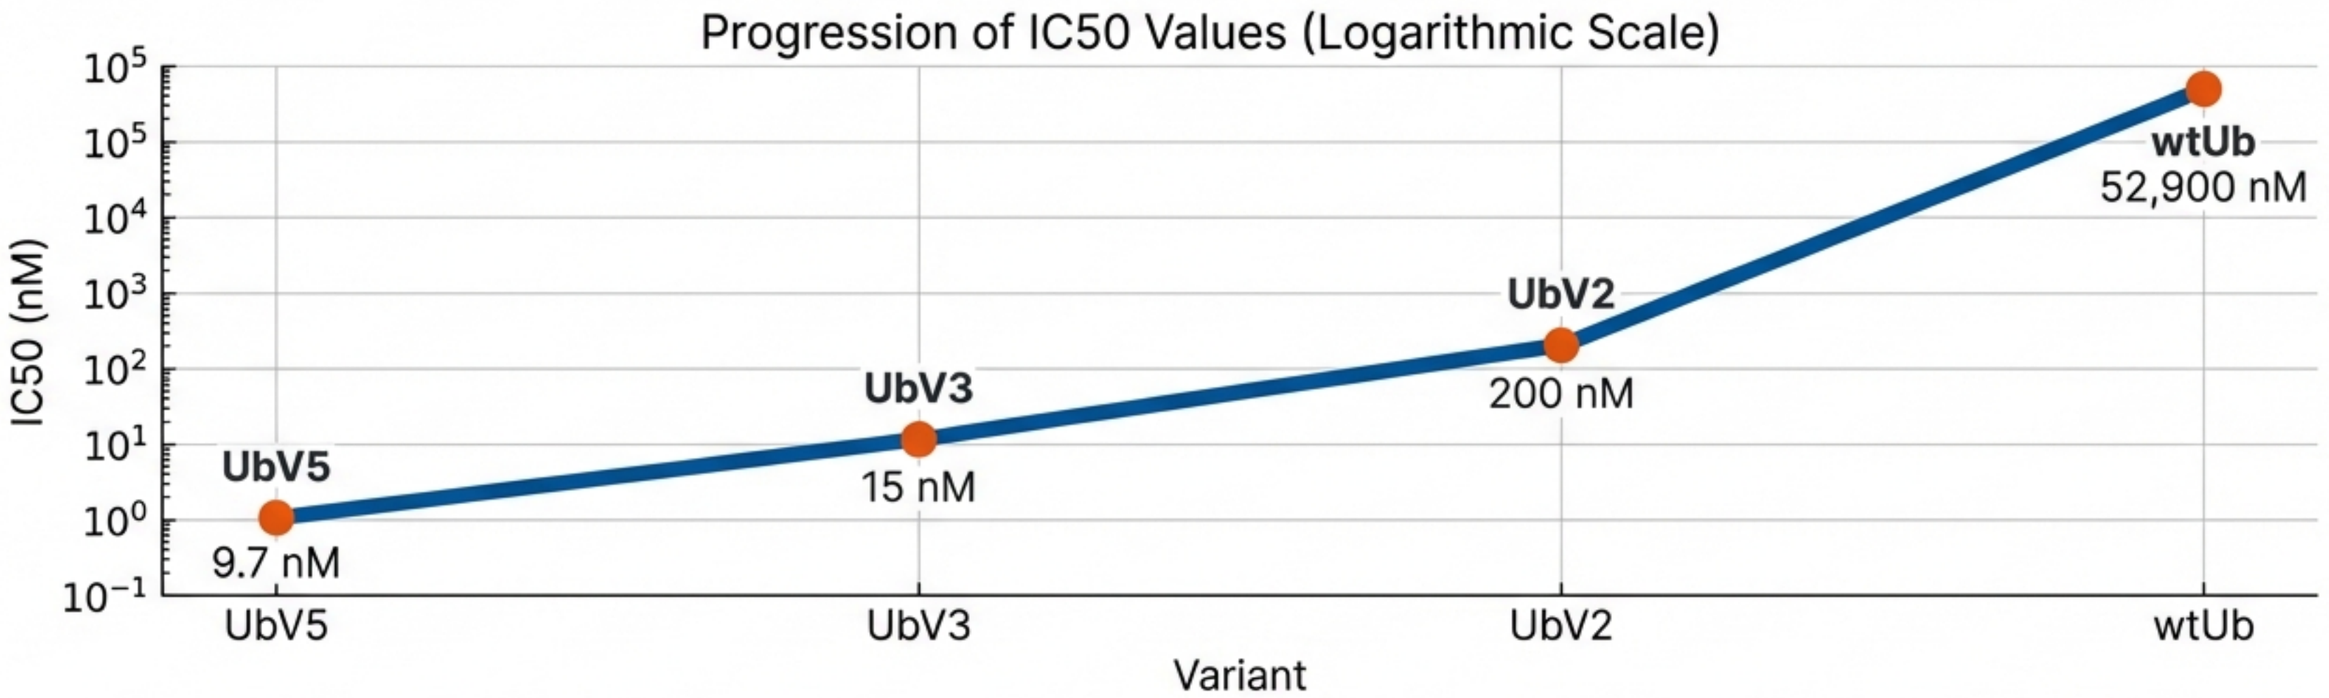


Target:
The LXGG recognition site where PLpro cuts Ubiquitin chains.

Mutation R74N & G75S
R74N reduces steric hindrance while keeping polar attraction. G75S increases local electrostatic interaction.

The Result:
Affinity (KD): 1.5 nM (27,500-fold enhancement).
Potency (IC50): 9.7 nM (5,500-fold efficiency).
Status: World-Class Binder.

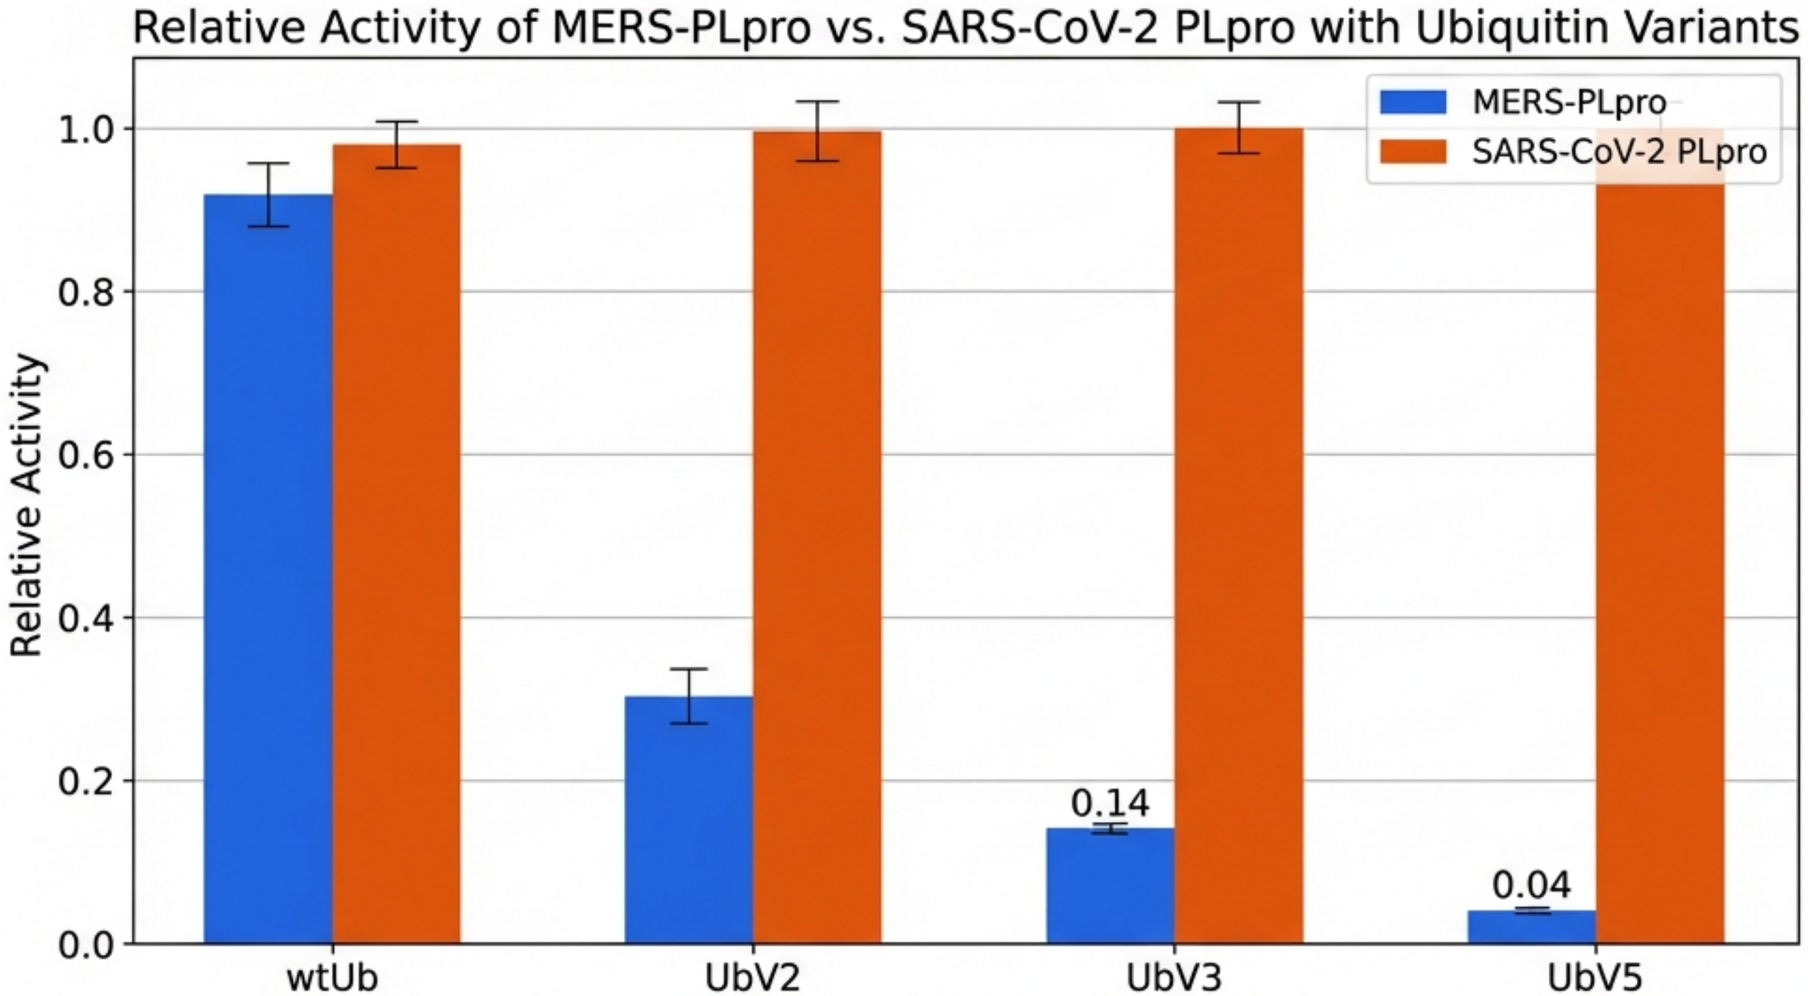
Quantifying the Escalation: 52,000 nM to 1.5 nM



Variant	Mutation Focus	IC50 (Potency)	KD (Affinity)	Fold Improvement
Wild Type (wtUb)	None	**52,900 nM**	40,750 nM	Baseline
UbV2	HCS1 (Core)	200 nM	220 nM	250x
UbV3	+ FBI (Finger)	15 nM	2.77 nM	3,500x
UbV5	+ UCC (Lock)	9.7 nM	**1.50 nM**	27,500x

Precision Targeting: High Selectivity for MERS-CoV

The correlation network is specific to MERS, preventing off-target binding.

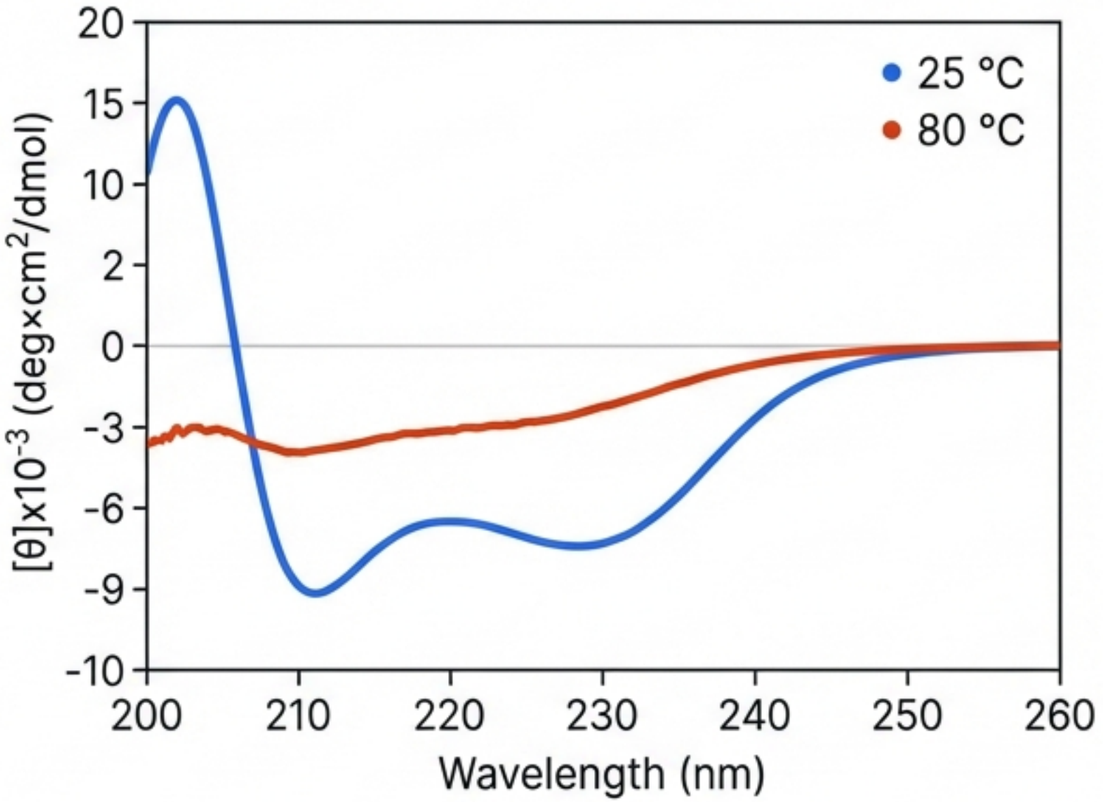


Why this matters:
MERS and SARS-CoV-2
MERS and SARS-CoV-2 share structural similarities, but their *dynamic networks* differ.

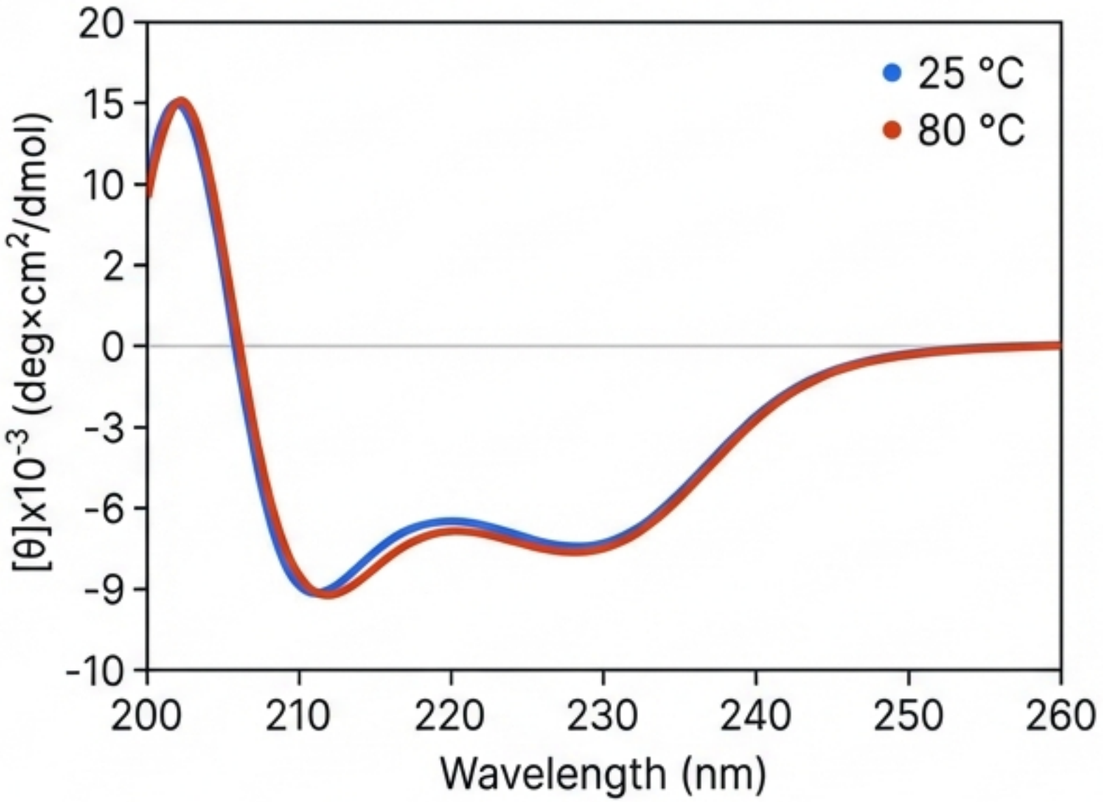
UbV5 targets the unique dihedral correlations of MERS, sparing other enzymes.

The Rational Advantage: Stability at 80°C

Phage Display Variant (15 mutations) - Unstable



Rational Design Variant (5 mutations) - Stable

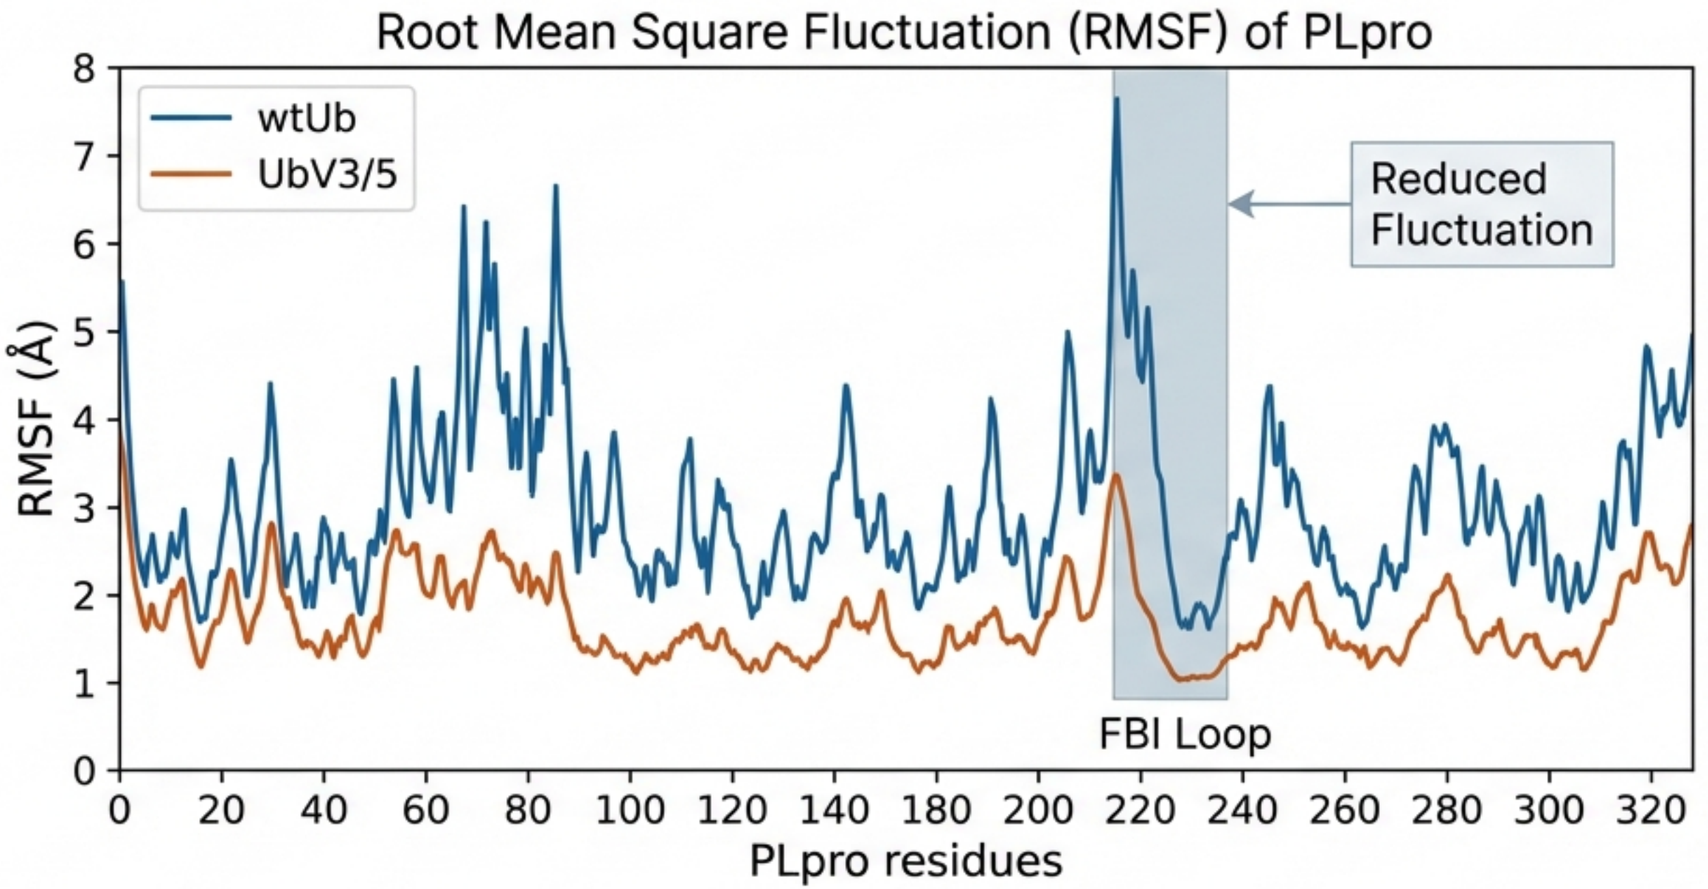


Minimizing Mutations = Maximizing Stability

Unlike competitors that require 15 mutations and fall apart at high heat, UbV5 retains full structural inigrity at 80°C with only 5 targeted mutations.

Freezing the Machine: Entropy and RMSF Reduction

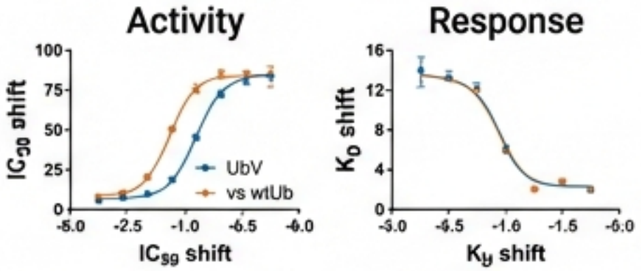
The biophysics of super-binding.



Mechanism of Action: The mutations act as a molecular clamp. By targeting 'hub' residues in the correlation network, UbV5 reduces the dihedral entropy of the PLpro interface, effectively 'freezing' the enzyme in a bound state.

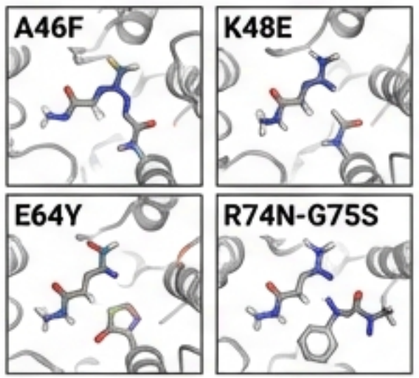
The Design Loop: A Repeatable Platform for Therapeutics

Validation:
Experimental Assay (IC50 / KD)



Experimental validation

Design: Rational Mutation
(Force Distribution Analysis)



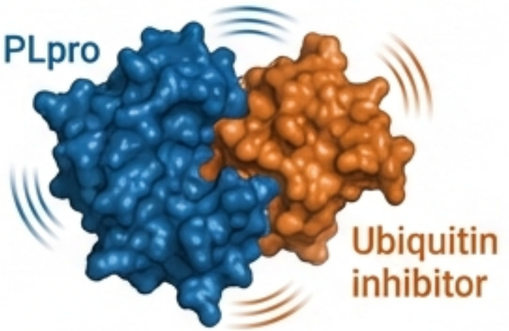
Computational design

Re-inform design

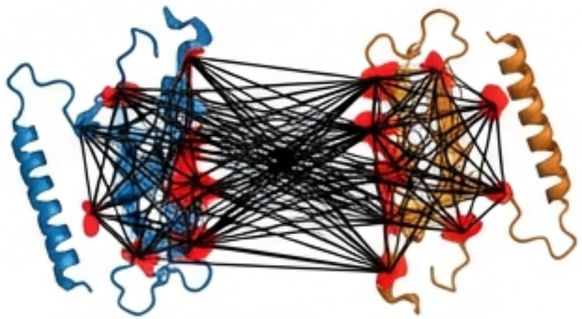
Highly interactive residues on complex interface

Hotspot ID: Identify Correlated "Hub" Residues (r > 0.3)

Simulation:
MD Simulation (500ns)



Network Analysis: Map Dihedral Angle Correlations

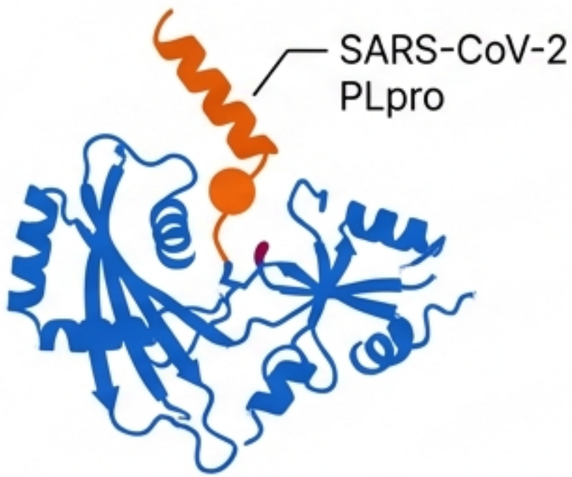


Side Chain Dihedral Correlation Network

This workflow is not specific to MERS; it is a generalizable platform for optimizing any Protein-Protein Interaction (PPI)

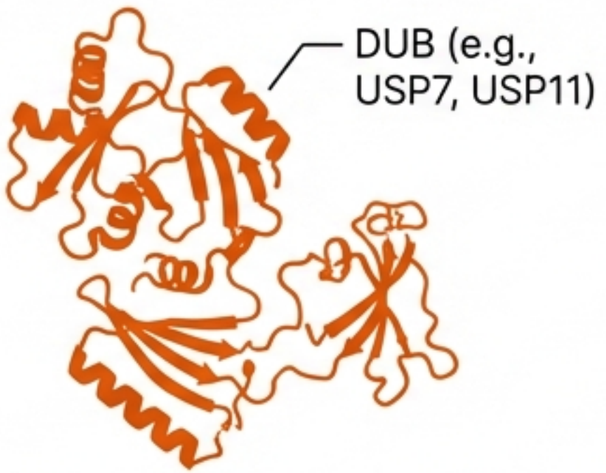
Beyond MERS: Implications for Future Therapeutics

COVID-19 (SARS-CoV-2)



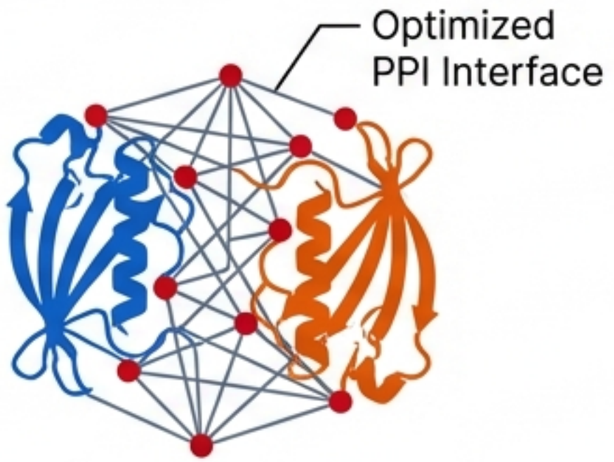
The workflow can be retargeted to the unique correlation networks of SARS-CoV-2 PLpro, which has distinct inhibitor specificity.

Oncology (DUBs)



Targeting Deubiquitinases (e.g., USP7, USP11) implicated in cancer progression and p53 regulation.

General PPIs



Replacing trial-and-error screening (6,000+ variants) with predictive design to optimize signaling and enzymatic pathways.

A New Standard for Protein Inhibitor Design

Unmatched Potency

27,500-fold affinity increase (1.5 nM).

Significant enhancement in binding strength over wild-type Ubiquitin.

Superior Stability

Thermostable at 80°C (only 5 mutations)

Remarkable structural integrity and resistance to denaturation.

Rational Efficiency

Predictive Network Analysis > Random Screening

Achieves results significantly faster and with fewer candidates than traditional methods.

UbV5 represents a potent lead candidate designed via the “Invisible Networks” of protein dynamics.
